Regularization

1. Overfitting

- Underfitting, or high bias, is when the form of our hypothesis function h maps **poorly** to the trend of the data.
- Overfitting, or high variance, is caused by a hypothesis function that fits the available data but does not generalize well to predict new data.

Addressing

- Reduce the number of features (manually select, model selection).
- Regularization (keep all the features, but reduce the magnitude of parameters).

2. Regularized Linear Regression

$$\min_{\theta} \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n \theta_j^2 \right], \text{ where } h_{\theta}(x) = \theta^T x$$

• Normal equation

$$\theta = (X^TX + \lambda \cdot L)^{-1}X^Ty \text{where } L = \begin{bmatrix} 0 & & & \\ & 1 & & \\ & & \ddots & \\ & & & 1 \end{bmatrix}$$

Proof

$$\left\{ \begin{array}{ll} \frac{\partial}{\partial \theta_j} J(\theta) = \frac{1}{m} \sum_{k=1}^m (\theta^T x^{(k)} - y^{(k)}) x_j^{(k)} & (j=0) \\ \frac{\partial}{\partial \theta_i} J(\theta) = \frac{1}{m} \sum_{k=1}^m (\theta^T x^{(k)} - y^{(k)}) x_j^{(k)} + \frac{\lambda}{m} \theta_j & (j\in N^+) \end{array} \right. \\ \Rightarrow \nabla_{\theta} J(\theta) = \frac{1}{m} (X^T X \theta - X^T y) + \frac{\lambda}{m} L \theta_j +$$

3. Regularized Logistic Regression

$$\min_{\theta} \left[-\frac{1}{m} \sum_{i=1}^{m} \left(y^{(i)} \mathrm{log} h_{\theta}(x^{(i)}) + (1-y^{(i)}) \mathrm{log} (1-h_{\theta}(x^{(i)})) \right) + \frac{\lambda}{2m} \sum_{j=1}^{n} \theta_{j}^{2} \right]$$

4. MLE & MAP

Preliminaries

- Assume data are generated via $d \sim p(d; \theta)$
- $D = \{d^{(i)}\}_{i=1,2,\cdots,m}$, where $d^{(i)}$ is i.i.d. (independent of others and same distribution).
- Goal: Estimate parameter θ that best models the data.

Maximum Likelihood Estimation (MLE)

- $\begin{array}{l} \bullet \ \ \text{Likelihood:} \ L(\theta) = p(D;\theta) = \prod_{i=1}^m p(d^{(i)};\theta) \\ \bullet \ \ \text{MLE typically maximizes the } \log \text{likelihood } l(\theta). \\ \bullet \ \ \theta_{MLE} = \arg\max_{\theta} \ \sum_{i=1}^m \log p(d^{(i)};\theta) \\ \end{array}$

Maximum-a-Posteriori Estimation (MAP)

- Posterior probability of θ is $p(\theta|D) = \frac{p(\theta)p(D|\theta)}{p(D)}$
- $p(\theta)$ is prior probability of θ , where p(D) is probability of the data.
- MAP usually maximizes the \log of the posteriori probability $\theta_{MAP} = \arg\max_{\theta} \ \left(\log p(\theta) + \sum_{i=1}^{m} \log p(d^{(i)}|\theta)\right)$

Linear Regression

1. MLE

- Suppose $y^{(i)} = \theta^T x^{(i)} + \epsilon^{(i)}, \text{ where } \epsilon \sim \mathcal{N}(0, \sigma^2)$
- Normal Distribution $p(x; \mu, \sigma) = \frac{1}{(2\pi\sigma^2)^{1/2}} \exp\left(-\frac{1}{2\sigma^2}(x-\mu)^2\right)$ $p(d^{(i)}; \theta) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2\sigma^2}(y^{(i)} \theta^T x^{(i)})^2\right) \Rightarrow \log p(d^{(i)}; \theta) = \log\frac{1}{\sigma\sqrt{2\pi}} \frac{1}{2\sigma^2}(y^{(i)} \theta x^{(i)})^2$ $\theta_{MLE} = \arg\min_{\theta} \sum_{i=1}^m (y^{(i)} \theta^T x^{(i)})^2$

2. MAP

- Suppose $\epsilon \sim \mathcal{N}(0, \sigma^2), \theta \sim \mathcal{N}(0, \lambda^2 I)$
- $\text{ Multivariate normal distribution } p(x;\mu,\Sigma) = \frac{1}{(2\pi)^{n/2}|\Sigma|^{1/2}} \exp\left(-\frac{1}{2}(x-\mu)^T \Sigma^{-1}(x-\mu)\right) \\ \text{ where } \mu \in \mathbb{R}^n, \ \Sigma \in \mathbb{R}^{n \times n} \text{ is symmetric and positive semidefinite} \\ \bullet \ p(\theta) = \frac{1}{(\sqrt{2\pi}\lambda)^n} \exp(-\frac{1}{2\lambda}\theta^T\theta) \Rightarrow \log \ p(\theta) = n \log \frac{1}{\sqrt{2\pi}\lambda} \frac{\theta^T\theta}{2\lambda^2} \\ \bullet \ \theta_{MAP} = \arg \min_{\theta} \left\{ \sum_{i=1}^m (y^{(i)} \theta^T x^{(i)})^2 + \frac{\theta^T\theta}{2\lambda^2} \right\}$

3. MLE vs MAP

- MLE (unregularized solution) vs MAP (regularized solution)
- The prior distribution acts as a regularizer in MAP estimation

Logistic Regression

Similar conclusion as above.
