Linear Regression

Basics

- Linear hypothesis: $h(x)=\theta_1x+\theta_0,\ \theta_i (i=1,2\ {\rm for\ 2D\ cases}).$
- · cost function:

$$J(\theta) = \frac{1}{2} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2, \quad h_{\theta}(x) = \sum_{i=0}^n \theta_i x_i = \theta^T x$$

- best choice for $\theta = \arg\min_{\theta} \ J(\theta)$

Gradient Descent (GD) Algorithm

Algorithm.

Given a starting point \theta in dom J
while converence criterion is satisfied
Calculate gradient \nabla J(\theta)
Update \theta \leftarrow \theta - \alpha\nabla J(\theta)

 θ Is usually initialized randomly, and α is so-called learning rate.

· For linear regression,

$$\begin{split} \theta_j &\leftarrow \theta_j - \alpha \frac{\partial J(\theta)}{\partial \theta_j}, \ \forall j = 0, 1, \cdots, n, \ x_0^{(i)} = 1 \\ \frac{\partial J(\theta)}{\partial \theta_j} &= \frac{\partial}{\partial \theta_j} \frac{1}{2} \sum_{i=1}^m (\theta^T x^{(i)} - y^{(i)})^2 \\ &= \frac{\partial}{\partial \theta_j} \frac{1}{2} \sum_{i=1}^m (\sum_{j=0}^n \theta_j x_j^{(i)} - y^{(i)})^2 \\ &= \sum_{i=1}^m (\theta^T x^{(i)} - y^{(i)}) x_j^{(i)} \end{split}$$

- Another commonly used form $J(\theta) = \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) y^{(i)})^2.$
- ullet m is introduced to scale the objective function to deal with differently sized training set.

Matrix Form

$$X = \left[\begin{array}{c} (x^{(1)})^T \\ \vdots \\ (x^{(m)})^T \end{array} \right], Y = \left[\begin{array}{c} y^{(1)} \\ \vdots \\ y^{(m)} \end{array} \right] J(\theta) = \frac{1}{2} \sum_{i=1}^m (\theta^T x^{(i)} - y^{(i)})^2 = \frac{1}{2} (X\theta - Y)^T (X\theta - Y)$$

- Minimize $J(\theta) = \frac{1}{2} (Y - X\theta)^T (Y - X\theta)$

$$\begin{split} \nabla_{\theta}J(\theta) &= \nabla_{\theta}\frac{1}{2}(Y - X\theta)^T(Y - X\theta) \\ &= \frac{1}{2}\nabla_{\theta}tr(Y^TY - Y^TX\theta - \theta^TX^TY + \theta^TX^TX\theta) \\ &= \frac{1}{2}\nabla_{\theta}tr(\theta^TX^TX\theta) - X^TY \\ &= \frac{1}{2}(X^TX\theta + X^TX\theta) - X^TY \\ &= X^TX\theta - X^TY \end{split}$$

Theorem. Normal Equation

The matrix A^TA is invertible if and only if the columns of A are linearly independent. In this case, there exists only one least-squares solution.

$$\theta = (X^T X)^{-1} X^T Y$$
