Logistic Regression

- · Classification problem is similar to predict only a small number of discrete values instead of continuous values.
- 1. Logistic Function (Sigmoid Function)

$$g(z) = \frac{1}{1 + e^{-z}}$$

Properties

- Bound: $g(z) \in (0,1)$
- Symmetric: 1 g(z) = g(-z)
- Gradient: q'(z) = q(z)(1 q(z))
- 2. Logistic Regression

$$h_{\theta}(x) = g(\theta^T x) = \frac{1}{(1+e^{-\theta^T x})}$$

- $\begin{array}{l} \bullet \ \theta^T x \text{ is called score. } h_\theta \text{ is called logistic regression.} \\ \bullet \ Pr(Y=1|X=x;\theta) = h(\theta) = \frac{1}{1+e^{-\theta^T x}} \\ \bullet \ Pr(Y=0|X=x;\theta) = 1 h_\theta(x) = \frac{1}{1+e^{\theta^T x}} \end{array}$

Decision Boundary

- $Pr(Y=1|X=x;\theta) = Pr(Y=0|X=x;\theta) \Rightarrow \theta^T x = 0$
- : The decision boundary is a linear hyperplane.
- The score $\theta^T x$ is also a measure of distance x from the hyperplane.

Probability Mass Function

$$p(y|x;\theta) = Pr(Y = y|X = x;\theta) = (h_{\theta}(x))^{y}(1 - h_{\theta}(x))^{1-y}, \text{ where } y \in \{0,1\}$$

$$p(y|x;\theta) = \frac{1}{1 + exp(-y\theta^Tx)}, \text{where } y \in \{-1,1\} \text{ instead of } y \in \{0,1\},$$

- Maximize the log likelihood $L(\theta) = \prod_{i=1}^m p(y|x;\theta)$ $l(\theta) = \log L(\theta) = \sum_{i=1}^m (y^{(i)} \log h_{\theta}(x^{(i)}) + (1-y^{(i)}) \log (1-h_{\theta}(x^{(i)})))$, still assume $y \in \{-1,1\}$

$$\frac{\partial}{\partial \theta_{j}} l(\theta) = \sum_{i=1}^{m} \frac{y^{(i)} - h_{\theta}(x^{(i)})}{h_{\theta}(x^{(i)})(1 - h_{\theta}(x^{(i)}))} \cdot \frac{\partial h_{\theta}(x^{(i)})}{\partial \theta_{j}} = \sum_{i=1}^{m} (y^{(i)} - h_{\theta}(x^{(i)})) x_{j}^{(i)}$$

1

3. Newton's Method

Properties

- · Highly dependent on initial guess
- Quadratic convergence once it is sufficiently close to x^{st}
- If f'=0, only has linear convergence
- Is not guaranteed to convergence at all, depending on function or initial guess

Update

$$x \leftarrow x - \frac{f'(x)}{f''(x)}$$

• For $l:\mathbb{R}^n \to \mathbb{R}$,

$$\theta \leftarrow \theta - H^{-1} \nabla_{\theta} l(\theta), \text{ where } H_{i,j} = \frac{\partial^2 l(\theta)}{\partial \theta_i \partial \theta_j}$$

Multiclass Classification

- · Transformation to binary
 - One-vs.-rest (OvR, train a single classifier per class, with the samples of that class as positive samples and all other samples as negative ones)

$$\star \ y^* = \operatorname{argmax} f_k(x)$$

- $\begin{array}{l} \star \ \ y^* = \operatorname*{argmax}_k f_k(x) \\ \star \ \ f_k(x) \ \text{implies hight robability that} \ x \ \text{is in class} \ k. \end{array}$
- One-vs.-one (OvO, to train K(K-1)/2 binary classifiers)

$$\star y^* = \operatorname{argmax}(\sum_t f_{s,t}(x))$$

- $\begin{array}{l} \star \ \ y^* = \mathop{\rm argmax}_s(\sum_t f_{s,t}(x)) \\ \star \ \ f_{s,t}(x) \ \ \text{implies that label s has higher probability than label t.} \end{array}$
- · Extension from binary
- · Hierarchical classification

4. Softmax Regression

$$\begin{split} l(\theta) &= \sum_{i=1}^{m} \mathrm{log} p(y^{(i)}|x^{(i)};\theta) \\ &= \sum_{i=1}^{m} \mathrm{log} \prod_{k=1}^{K} \left(\frac{exp(\theta^{(k)^{T}}x^{(i)})}{\sum_{k'=1}^{K} exp(\theta^{(k')^{T}}x^{(i)})} \right)^{\mathbb{I}(y^{(i)}=k)} \end{split}$$

• where $\mathbb{I}: \{True, False\} \rightarrow \{0,1\}$ is an indicator function.
