Naive Bayes and EM Algorithm

Theorem.

Bayes' Theorem

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

• If X and Y are both continuous, then $f_{X|Y=y}(x) = \frac{f_{Y|X=x}(y)f_X(x)}{f_Y(y)}$

Law of total probability

If $\{B_n: n=1,2,3,\ldots\}$ is a finite or countably infinite partition of a sample space.

$$P(A) = \sum_n P(A \mid B_n) P(B_n)$$

Warm up

- In linear regression and logistic regression, x and y are linked through (deterministic) hypothesis function
- Given a set of training data $\mathcal{D}=\{x^{(i)},y^{(i)}\}_{i=1,\cdots,m},\ P(\mathcal{D})=\prod_{i=1}^m p_{X|Y}(x^{(i)}|y^{(i)})p_Y(y^{(i)})$

Gaussian Distribution

- Normal Distribution $p(x;\mu,\sigma)=\frac{1}{(2\pi\sigma^2)^{1/2}}\exp\left(-\frac{1}{2\sigma^2}(x-\mu)^2\right)$
- Multivariate normal distribution $p(x; \mu, \Sigma) = \frac{1}{(2\pi)^{n/2} |\Sigma|^{1/2}} \exp\left(-\frac{1}{2}(x-\mu)^T \Sigma^{-1}(x-\mu)\right)$
- where $\mu \in \mathbb{R}^n$, $\Sigma \in \mathbb{R}^{n \times n}$ is symmetric and postitive semidefinite

Gaussian Discriminant Analysis (GDA)

- $Y \sim Bernoulli(\psi)$
- $\bullet \ \ p_{X\mid Y}(x\mid 0) = \tfrac{1}{(2\pi)^{n/2}|\Sigma|^{1/2}} \exp\left(-\tfrac{1}{2}\left(x-\mu_0\right)^T \Sigma^{-1}\left(x-\mu_0\right)\right)$
- $p_{X|Y}(x \mid 1) = \frac{1}{(2\pi)^{n/2}|\Sigma|^{1/2}} \exp\left(-\frac{1}{2}(x \mu_1)^T \Sigma^{-1}(x \mu_1)\right)$

$$\ell\left(\psi, \mu_0, \mu_1, \Sigma\right) = \sum_{i=1}^m \log p_{X|Y}\left(x^{(i)} \mid y^{(i)}; \mu_0, \mu_1, \Sigma\right) + \sum_{i=1}^m \log p_Y\left(y^{(i)}; \psi\right)$$

• Maximizing $\ell(\psi, \mu_0, \mu_1, \Sigma)$ to get the solutions:

$$\begin{split} \psi &= \frac{1}{m} \sum_{i=1}^m \mathbf{1} \left\{ y^{(i)} = 1 \right\} \\ \mu_0 &= \sum_{i=1}^m \mathbf{1} \left\{ y^{(i)} = 0 \right\} x^{(i)} / \sum_{i=1}^m \mathbf{1} \left\{ y^{(i)} = 0 \right\} \\ \mu_1 &= \sum_{i=1}^m \mathbf{1} \left\{ y^{(i)} = 1 \right\} x^{(i)} / \sum_{i=1}^m \mathbf{1} \left\{ y^{(i)} = 1 \right\} \\ \Sigma &= \frac{1}{m} \sum_{i=1}^m \left(x^{(i)} - \mu_{y^{(i)}} \right) \left(x^{(i)} - \mu_{y^{(i)}} \right)^T \end{split}$$

• Given a test data sample x, we can calculate

$$\begin{split} p_{Y|X}(y = 1 \mid x) &= \frac{p_{X|Y}(x \mid 1)p_Y(1)}{p_X(x)} \\ &= \frac{p_{X|Y}(x \mid 1)p_Y(1)}{p_{X|Y}(x \mid 1)p_Y(1) + p_{X|Y}(x \mid 0)p_Y(0)} \\ &= \frac{1}{1 + \frac{p_{X|Y}(x \mid 0)p_Y(0)}{p_{X|Y}(x \mid 1)p_Y(1)}} \end{split}$$

Naive Bayes

Assumption.

For $\forall j \neq j' \ X_j$ and $X_{j'}$ are conditionally independent given Y, i.e., $P\left(Y=y, X_1=x_1, \cdots, X_n=x_n\right) = p(y) \prod_{j=1}^n p_j\left(x_j \mid y\right)$

 $\text{ MLE } \ell(\Omega) = \textstyle \sum_{i=1}^m \log p\left(y^{(i)}\right) + \textstyle \sum_{i=1}^m \sum_{j=1}^n \log p_j\left(x_j^{(i)} \mid y^{(i)}\right)$ Theorem.

$$p(y) = \frac{count(y)}{m}, p_j(x \mid y) = \frac{count_j(x \mid y)}{count(y)} \\ count(y) = \sum_{i=1}^m 1(y^{(i)} = y), \ count_j(x \mid y) \\ = \sum_{i=1}^m 1(y^{(i)} = y \land x_j^{(i)} = y) \\ = \sum_{i=1}^m 1(y^{(i)} = y) \\ = \sum_{i=1}^m 1(y^{(i)}$$

Classification by NB

Laplace Smoothing

• There may exist some feature, e.g., X_{j^*} , such that $X_{j^*} = 1$ for some x^* may never happen in the training data. (i.e., $p_{j^*}\left(x_{j^*} = 1 \mid y\right) = \frac{\sum_{i=1}^m \mathbf{1}\left(y^{(i)} = y \wedge x_{j^*}^{(i)} = 1\right)}{\sum_{i=1}^m \mathbf{1}\left(y^{(i)} = y\right)} = 0, \forall y = 0, 1$

•
$$:p(y \mid x) = \frac{p(y) \prod_{j=1}^{n} p_j(x_j \mid y)}{\sum_{y} \prod_{j=1}^{n} p_j(x_j \mid y) p(y)} = \frac{0}{0}, \forall y = 0, 1$$

Laplace Smoothing

$$\begin{split} p(y) &= \frac{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right) + 1}{m+k} \\ p_{j}(x \mid y) &= \frac{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \wedge x_{j}^{(i)} = x \right) + 1}{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right) + v_{j}} \end{split}$$

where k is number of the possible values of y(k = 2 in our case), and v_j is the number of the possible values of the j-th feature ($v_j=2$ for $\forall j = 1, \dots, n$ in our case)

Multinomial Distribution

Assumption

Each training sample involves a different number of features

$$x^{(i)} = \left[x_1^{(i)}, x_2^{(i)}, \cdots, x_{n_i}^{(i)}\right]^{\mathrm{T}}$$

The j-th feature of $x^{(i)}$ takes a finite set of values, $x_j^{(i)} \in \{1, 2, \cdots, v\}$

- For example, $x_j^{(i)}$ indicates the j-th word in the email. • Let $p(t\mid y)=P(X_j=t|Y=y)$

$$\begin{split} &P\left(Y=y^{(i)}\right)=p\left(y^{(i)}\right)\\ &P\left(X=x^{(i)}\mid Y=y^{(i)}\right)=\prod_{i=1}^{n_i}p\left(x_j^{(i)}\mid y^{(i)}\right) \end{split}$$

Problem.

$$\begin{array}{ll} \max & \ell(\Omega) = \log p\left(y^{(i)}\right) \prod_{i=1}^m p(x^{(i)} \mid y^{(i)}) = \sum_{i=1}^m \sum_{j=1}^{n_i} \log p(x_j^{(i)} \mid y^{(i)}) + \sum_{i=1}^m \log p\left(y^{(i)}\right) \\ \mathrm{s.t.} & \sum_{y \in \{0,1\}} p(y) = 1, \\ & \sum_{t=1}^v p(t \mid y) = 1, \forall y = 0, 1 \\ & p(y) \geq 0, \forall y = 0, 1 \\ & p(t \mid y) \geq 0, \forall t = 1, \cdots, v, \forall y = 0, 1 \end{array}$$

• Solution

$$\begin{split} p(t \mid y) &= \frac{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right) \text{ count }^{(i)}(t)}{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right) \sum_{t=1}^{v} \text{ count }^{(i)}(t)} \\ p(y) &= \frac{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right)}{m} \\ \text{where count }^{(i)}(t) &= \sum_{j=1}^{n_i} \mathbf{1} \left(x_j^{(i)} = t \right) \end{split}$$

• Laplace smoothing

$$\begin{split} \psi(y) &= \frac{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right) + 1}{m+k} \\ \psi(t \mid y) &= \frac{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right) \operatorname{count}^{(i)}(t) + 1}{\sum_{i=1}^{m} \mathbf{1} \left(y^{(i)} = y \right) \sum_{t=1}^{v} \operatorname{count}^{(i)}(t) + v} \end{split}$$

Expectation Maximization (EM) Algorithm

Def. Latent Variable.

$$\begin{split} \ell(\theta) &= \log \prod_{i=1}^m p(x^{(i)}; \theta) \\ &= \sum_{i=1}^m \log \sum_{z^{(i)} \in \Omega} p(x^{(i)}, z^{(i)}; \theta) \end{split}$$

where $z^{(i)} \in \Omega$ is so-called *latent variable*.

- Basic idea of EM algorithm
 - Repeatedly construct a lower-bound on ℓ (E-step)
 - * E-Step estimates the parameters by observing the data and the existing model, and then use this estimated parameter value to calculate the expected value of the likelihood function.
 - Then optimize that lower-bound (M-step)
 - * M-step finds the corresponding parameters when the likelihood function is maximized. Since the algorithm guarantees that the likelihood function will increase after each iteration, the function will eventually converge.
- Let Q_i denotes the distribution of z for i-th sample. Thus, $\sum_{z\in\Omega}Q_i(z)=1,$ $Q_i(z)\geq 0$

$$\begin{split} \ell(\theta) &= \sum_{i=1}^{m} \log \sum_{z^{(i)} \in \Omega} Q_{i}\left(z^{(i)}\right) \frac{p\left(x^{(i)}, z^{(i)}; \theta\right)}{Q_{i}\left(z^{(i)}\right)} \\ &= \sum_{i=1}^{m} \log E \left\lceil \frac{p\left(x^{(i)}, z^{(i)}; \theta\right)}{Q_{i}\left(z^{(i)}\right)} \right\rceil \end{split}$$

Thereom. Jesen's Inequality.

Assume f be a concave function.

$$f(E[X]) \ge E(f(X))$$

• Since $\log(\cdot)$ is a concave function, according to Jensen's inequality, we have

- Tighten the lower bound, the equality holds when $\frac{p(x^{(i)},z^{(i)};\theta)}{Q_i(z^{(i)})}=c$, where cis a constant.
- Therefore, $\sum_{z^{(i)} \in \Omega} p(x^{(i)}, z^{(i)}; \theta) = c \sum_{z^{(i)} \in \Omega} Q_i(z) = c$

$$\begin{split} Q_i\left(z^{(i)}\right) &= \frac{p\left(x^{(i)}, z^{(i)}; \theta\right)}{c} \\ &= \frac{p\left(x^{(i)}, z^{(i)}; \theta\right)}{\sum_{z^{(i)} \in \Omega} p\left(x^{(i)}, z^{(i)}; \theta\right)} \\ &= \frac{p\left(x^{(i)}, z^{(i)}; \theta\right)}{p\left(x^{(i)}; \theta\right)} \\ &= p\left(z^{(i)} \mid x^{(i)}; \theta\right) \end{split}$$

Algorithm.

- $\begin{array}{l} \text{1. (E-step) For each } i, \, \text{set } Q_i(z^{(i)}) := p(z^{(i)} \mid x^{(i)}; \theta) \\ \text{2. (M-step) set } \theta := \arg\max_{\theta} \sum_{i} \sum_{z^{(i)} \in \Omega} Q_i(z^{(i)}) \log \frac{p(x^{(i)}, z^{(i)}; \theta)}{Q_i(z^{(i)})} \end{array}$

EM in NB

Naive Bayes with Missing Labels

- When labels are given $\ell(\theta) = \log p(x,y) = \sum_{i=1}^m \log \left[\ p(y^{(i)}) \prod_{j=1}^n p_j(x_j^{(i)} \mid y^{(i)}) \right]$
- When labels are missed $\ell(\theta) = \log p(x) = \sum_{i=1}^{m} \log \sum_{y=1}^{k} \left[p(y) \prod_{i=1}^{n} p_j(x_j^{(i)} \mid y) \right]$

Applying EM to NB

- (E-step) For each $i=1,\cdots,m$ and $y=1,\cdots,k$ set
 - Relabel y by $Q_i(y)$.

$$Q_{i}(y) = p\left(y^{(i)} = y \mid x^{(i)}\right) = \frac{p(y)\prod_{j=1}^{n}p_{j}\left(x_{j}^{(i)} \mid y\right)}{\sum_{y'=1}^{k}p\left(y'\right)\prod_{j=1}^{n}p_{j}\left(x_{j}^{(i)} \mid y'\right)}$$

- (M-step) Update the parameters (solved by Lagrange multiplier).
 - Use $\sum_{i=1}^{m} Q_i(y)$ to substitute the count(y)

$$\begin{split} p(y) &= \frac{1}{m} \sum_{i=1}^m Q_i(y), \quad \forall y \\ p_j(x \mid y) &= \frac{\sum_{i:x_j^{(i)} = x} Q_i(y)}{\sum_{i=1}^m Q_i(y)}, \quad \forall x, y \end{split}$$
